# Structure from Motion 

Computer Vision<br>CS 143, Brown

James Hays

## This class: structure from motion

- Recap of epipolar geometry
- Depth from two views
- Affine structure from motion

## Recap: Epipoles

- Point $x$ in left image corresponds to epipolar line l' in right image
- Epipolar line passes through the epipole (the intersection of the cameras' baseline with the image plane

## Recap: Fundamental Matrix

- Fundamental matrix maps from a point in one image to a line in the other

$$
\mathrm{l}^{\prime}=\mathrm{Fx} \quad \mathrm{l}=\mathrm{F}^{\top} \mathrm{x}^{\prime}
$$

- If $x$ and $x^{\prime}$ correspond to the same $3 d$ point $X$ :

$$
\mathrm{x}^{\prime \top} \mathrm{Fx}=0
$$

## Structure from motion

- Given a set of corresponding points in two or more images, compute the camera parameters and the 3D point coordinates

Camera 1 ?
$R_{1}, t_{1}$

? Camera 3
$R_{3}, t_{3}$

## Structure from motion ambiguity

- If we scale the entire scene by some factor $k$ and, at the same time, scale the camera matrices by the factor of $1 / k$, the projections of the scene points in the image remain exactly the same:

$$
\mathbf{x}=\mathbf{P X}=\left(\frac{1}{k} \mathbf{P}\right)(k \mathbf{X})
$$

It is impossible to recover the absolute scale of the scene!

## Structure from motion ambiguity

- If we scale the entire scene by some factor $k$ and, at the same time, scale the camera matrices by the factor of $1 / k$, the projections of the scene points in the image remain exactly the same
- More generally: if we transform the scene using a transformation $\mathbf{Q}$ and apply the inverse transformation to the camera matrices, then the images do not change

$$
\mathbf{x}=\mathbf{P X}=\left(\mathbf{P} \mathbf{Q}^{-1}\right)(\mathbf{Q X})
$$

## Projective structure from motion

- Given: $m$ images of $n$ fixed 3D points

$$
\text { - } \mathbf{x}_{i j}=\mathbf{P}_{i} \mathbf{X}_{j}, i=1, \ldots, m, \quad j=1, \ldots, n
$$

- Problem: estimate $m$ projection matrices $\mathbf{P}_{i}$ and $n$ 3D points $\mathbf{X}_{j}$ from the $m n$ corresponding points $\mathbf{x}_{i j}$

## Projective structure from motion

- Given: $m$ images of $n$ fixed 3D points
- $\mathbf{x}_{i j}=\mathbf{P}_{i} \mathbf{X}_{j}, \quad i=1, \ldots, m, \quad j=1, \ldots, n$
- Problem: estimate $m$ projection matrices $\mathbf{P}_{i}$ and $n$ 3D points $\mathbf{X}_{j}$ from the $m n$ corresponding points $\mathbf{x}_{i j}$
- With no calibration info, cameras and points can only be recovered up to a $4 \times 4$ projective transformation $\mathbf{Q}$ :
- $\mathbf{X} \rightarrow \mathbf{Q X}, \mathbf{P} \rightarrow \mathbf{P Q}^{-1}$

## Bundle adjustment

- Non-linear method for refining structure and motion
- Minimizing reprojection error
